

Computational Complexity – Homework 4

Discussed on 9 May 2016.

Exercise 4.1

Let us denote $\mathbf{DP} = \{L \mid \exists M, N \in \mathbf{NP} : L = M \setminus N\}$ the class of languages that are differences of two NP languages.

- (a) Show that $C = \{\langle G_1, k_1, G_2, k_2 \rangle \mid G_1 \text{ has a } k_1\text{-clique and } G_2 \text{ does not have any } k_2\text{-clique}\}$ is DP-complete.
- (b) Show that $\mathbf{MAX-CLIQUE} = \{\langle G, k \rangle \mid \text{the largest clique of } G \text{ is of size exactly } k\}$ is DP-complete.
- (c) It is unknown whether $\mathbf{MAX-CLIQUE}$ is in \mathbf{NP} . Show that if $\mathbf{P} = \mathbf{NP}$ then $\mathbf{MAX-CLIQUE}$ is in \mathbf{NP} and a largest clique can be found in polynomial time.

Exercise 4.2

- (a) Assume that $\mathbf{P} = \mathbf{NP}$. Show that then $\mathbf{EXP} = \mathbf{NEXP}$.

Remark: Assume that L is decided by some TM running in time $T(n)$ with $T(n)$ time-constructible and $T(n) \in \mathcal{O}(2^{cn})$ for some $c \geq 1$. Show that then

$$L_{\text{pad}} := \{x10^{T(|x|)}1 \mid x \in L\} \in \mathbf{NP}.$$

- * (b) Show that also $\mathbf{EXP} = \mathbf{NEXP}$ if only every unary NP-language is also in \mathbf{P} .

Remark: For $x \in \{0, 1\}^*$ let $\langle x \rangle$ be the natural number represented by x assuming lsbf. Given a language L which is decided in time $T(n)$ (with $T(n)$ time-constructible) show that

$$L_{\text{upad}} = \{1^{(\langle x \rangle |T(n)|)} \mid x \in L\} \in \mathbf{NP}$$

with $|T(n)| (\approx \lceil \log T(n) \rceil)$ the length of the lsbf representation of $T(n)$.

Exercise 4.3

Say that A is *linear-time reducible* to B if there is function f computable in time $\mathcal{O}(n)$ such that $x \in A \Leftrightarrow f(x) \in B$.

- Show that there is no P-complete problem w.r.t. linear-time reductions.

Hint: Use the time hierarchy theorem for \mathbf{DTIME} .

Exercise 4.4

A *two-person game* consists of a directed graph $G = (V_0, V_1, E)$ (called the *game graph*) whose nodes $V := V_0 \cup V_1$ are partitioned into two sets and a *winning condition*. We assume that every node $v \in V$ has a successor. The two players are called for simplicity player 0 and player 1. A *play* of the two is any finite or infinite path $v_1 v_2 \dots$ in G where v_1 is the starting node. If the play is currently in node v_i and $v_i \in V_0$, then we assume that it is the turn of player 0 to choose v_{i+1} from the successors of v_i ; if $v_i \in V_1$, player 1 determines the next move. The winning condition defines when a play is won by player 0. E.g.:

- In a *reachability game* the winning condition is simply defined by a subset $T \subseteq V_0 \cup V_1$ (*targets*) of the nodes of G , and a play is won by player 0 if it visits T within $n - 1$ moves (where n is the total number of nodes of G). Hence, player 1 wins a play if he can avoid visiting T for at least $n - 1$ moves.
- In a *revisiting game* player 0 wins a play $v_1 v_2 \dots$ if the first node v_i which is visited a second time belongs to player 0, i.e., $v_i \in V_0$; otherwise player 1 wins the play.

We say that *player i wins node s* if he can choose his moves in such a way that he wins any play starting in s .

Example: Consider the following game graph where nodes of V_0 (V_1) are of circular (rectangular) shape:

In the reachability game with $T = \{5\}$ player 0 can win node 4: if player 1 moves from 4 to 5, player 0 immediately wins; if player 1 moves from 4 to 2, then player 0 can win again by moving from 2 to 5. On the other hand, player 1 can win node 0 by choosing to always play from 0 to 1 and from 3 to 1.

In the revisiting game played on the same game graph, player 0 can win node 2: he moves from 2 to 5 and then on to 4; no matter how player 1 then chooses to move, the play will end in an already visited node which belongs to player 0. Player 1 can e.g. win node 3 by simply moving to node 1.

- (a) Consider a reachability game:

Show that one can decide in time polynomial in $\langle G, s, T \rangle$ if player 0 can win node s .

Hint: Starting in T compute the set of nodes from which player 0 can always reach T no matter how player 1 chooses his moves.

- (b) Consider a revisiting game:

Show that it is **PSPACE**-complete to decide for a given game graph G and node s if player 0 can win s .

Remarks:

- A game is called *determined* if every node is won by one of the two players.
Are reachability, resp. revisiting games determined?
- Assume that we change the definition of reachability game by dropping the restriction on the number of moves, i.e., player 0 wins a play if the play eventually reaches a state in T .
Does this change the nodes player 0 can win for a given game graph?

Exercise 4.5

An *alternating Turing machine* (ATM) $M = (\Gamma, Q_\forall, Q_\exists, \delta_0, \delta_1)$ is an NDTM $(\Gamma, Q_\forall \cup Q_\exists, \delta_0, \delta_1)$ except that (i) the control states are partitioned into sets Q_\forall and Q_\exists and (ii) the acceptance condition is defined as

follows:

Consider the configuration graph $G(M, x)$. We extend the partition of the control states to the configurations (nodes) of $G_{M,x}$: a configuration is in V_0 if its control state is in Q_{\exists} ; otherwise it is in V_1 . We then can consider the reachability game played on $G(M, x)$ by the players 0 and 1 where the target set is the set of accepting configurations. M accepts x iff player 0 wins the initial configuration in this reachability game. (For the sake of completeness, assume that every halting/accepting configuration is its unique successor.)

Example: Consider the following configuration graphs where accepting configurations have a second circle/rectangle drawn around them. In the left graph the corresponding ATM accepts the input while it rejects the input in the right example:

A language is decided by an ATM M if M accepts every $x \in L$ and rejects any $x \notin L$. The time and space required by an ATM is the time and space required by the underlying NDTM.

The class **AP** consists of all languages L which are decided by an ATM M running in time $T(n) \in \mathcal{O}(n^k)$ for some $k \geq 1$.

- (a) An *existential (universal)* ATM is an ATM with $Q_{\forall} = \emptyset$ ($Q_{\exists} = \emptyset$).

Show that any language $L \in \mathbf{AP}$ which is decided by an existential (universal) ATM is in **NP** (**coNP**).

- (b) Define **coAP** as usual: $L \in \mathbf{coAP}$ iff $\bar{L} \in \mathbf{AP}$.

Show or disprove that **AP** = **coAP**.

- (c) Show that **QBF** is in **AP**.

- (d) Show that any $L \in \mathbf{AP}$ is in **PSPACE**.

Remark: Adapt the recursive decision procedure for **QBF** \in **PSPACE** you have seen in the lecture.

Remark: Similarly as **AP**=**PSPACE**, one can show **APSPACE**=**EXPTIME**.
