Computational Complexity – Homework 9

Discussed on 31.05.2016.

Exercise 9.1

Given an undirected graph G = (V, E) we call $C \subseteq V$ a *(vertex) cover* of G if

 $\forall (u, v) \in E : u \in C \lor v \in C.$

In the following, we want to study the relation between several decision and function problems related to vertex cover. These are:

- $VC_D := \{ \langle G, k \rangle \mid G \text{ has a vertex cover of size at most } k \}.$
- MINVC_D := { $\langle G, k \rangle | G$ has a minimal vertex cover of size exactly k}.
- MINSOLVC_D := { $\langle G, C \rangle | C$ is a minimal vertex cover of G}.
- Calculate the minimal size $\min VC(G)$ of a vertex cover of G.
- Calculate a minimal vertex cover MinVC(G) of G.

Show:

- (a) MINSOLVC_D \leq_p MINVC_D.
- (b) MINSOLVC_D $\leq_p \overline{\text{VC}}_D$
- (c) $MinVC_D$ is **DP**-complete. (We have already discussed that MaxClique is **DP**-complete)
- (d) $\operatorname{VC}_D \leq_p \operatorname{MinVC}_D$ and $\overline{\operatorname{VC}}_D \leq_p \operatorname{MinVC}_D$.

Remark: You only have to show that such reductions exist.

(e) Assume that $\min VC(G)$ can be calculated in time T(|G|).

Give bounds on the time needed to decide $MINVC_D$ and $MINSOLVC_D$, resp. calculate MinVC(G).

In particular, show that, if T(n) is polynomial, then so are the other bounds.

- (f) Analogously to (e), give time bounds on the considered problems assuming that $\langle G, k \rangle \in$ MinVC_D (resp. $\langle G, k \rangle \in$ VC_D) can be decided in time T(|G|).
- (g) If $\operatorname{MinVC}_D \leq_p \operatorname{MinSolVC}_D$, then $\mathbf{PH} \subseteq \Sigma_1^p$.

Exercise 9.2

Let $\Phi = {\phi_1, \ldots, \phi_m}$ be a set of *m* Boolean expressions in the variables x_1, \ldots, x_n with the restriction that every expression involves at most 3 of these *n* variables.

Assume we choose a truth assignment u uniformly at random from $\{0,1\}^n$. Denote then by $\Pr[\phi_i]$ the probability that u satisfies ϕ_i .

- (a) Show that $\Pr[\phi_i]$ can be calculated in time polynomial in the length of ϕ_i .
- (b) Give a lower bound for the complexity of calculating probability of satisfying all ϕ_i ?
- (c) Let N be the random variable which counts the number of expressions ϕ_i satisfied by the random assignment u. Show that

$$\mathbb{E}[N] = \sum_{i=1}^{m} \Pr[\phi_i].$$

(d) We write $\mathbb{E}[N \mid u_1 = 0]$ for the expected number of expressions satisfied by a random assignment u which assigns 0 to x_1 . Similarly, define $\mathbb{E}[N \mid u_1 = 1]$. Show:

$$\mathbb{E}[N] = \frac{1}{2} \cdot (\mathbb{E}[N \mid u_1 = 0] + \mathbb{E}[N \mid u_1 = 1]).$$

- (e) Show that there is always a value b s.t. $\mathbb{E}[N \mid u_1 = b] \ge \mathbb{E}[N]$.
- (f) Give now a polynomial-time algorithms which computes an assignment which satisfies at least $\mathbb{E}[N]$ expressions of Φ .

Exercise 9.3

The decision version of the *traveling salesman problem* (short TSP) is defined as follows:

Given distances $d_{ij} \ge 0$ between n cities and a bound $B \ge 0$, decide if there is a tour of the cities of length at most B.

We denote the corresponding decision problem by TSP_D , i.e.,

$$\langle d_{1,1}, \ldots, d_{n,n}, B \rangle \in \text{TSP}_D$$
 iff there is TSP-tour w.r.t. (d_{ij}) of length at most B.

A Hamilton path in an undirected graph G = (V, E) is a path in G which visits every node exactly once. The corresponding decision problem HAMILTONPATH_D is known to be **NP**-complete.

(a) Show that the following is polynomial-time reduction from HP_D to TSP_D :

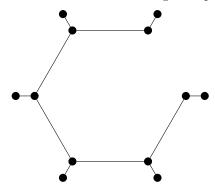

Given G = (V, E) with n = |V| and assume that $V = \{1, 2, ..., n\}$. Set $d_{i,j} := 1$ if the nodes *i* and *j* are connected by some edge, otherwise $d_{i,j} := n + 1$. Further, set B := 2n.

- (b) Show that *n*-approximating the optimal solution of TSP (i.e. finding a cycle at most n times longer than the optimal) is **NP**-hard.
- (c) We call a TSP-instance $\langle d_{1,1}, \ldots, d_{n,n}, B \rangle$ metric if $d_{ij} \leq d_{ik} + d_{kj}$ holds for all i, j, k.
 - Give an example of a graph G where the TSP-instance produced by the reduction above is not metric.
 - Modify the reduction such that it always yields a metric TSP-instance.

(d) The following algorithm for approximating the optimal solution of a <u>metric</u> TSP is by Christofides:

First, compute a minimal spanning tree $T = (V_T, E_T)$ of the complete graph K_n with distance matrix (d_{ij}) . Let O be the nodes of T which have odd degree (w.r.t. T!). Consider now the complete graph K_O consisting only of these nodes O, and calculate a minimal matching M for it, i.e., find a subset M of the edges of K_O s.t. every node is connected to exactly one other node (no loops) and the total weight of M, i.e., $\sum_{(i,j)\in M} d_{ij}$, is minimal. Add now the edges M to T yielding a multigraph G, i.e., assume that the original edges of T are colored black, while those of M are colored red. Still, the weight of an edge (i, j) in G is d_{ij} independent of its color. Calculate a Eulerian walk of G, i.e., a path of G which uses every edge, both black and red, of G exactly once. The approximation is then the tour embedded in the Eulerian walk.

- Convince yourself that every step of the algorithm by Christofides can be implemented in polynomial time (look it up on the Internet).
- Apply the algorithm by Christofides to the following example:

The coordinates of the inner nodes are $R \cdot (\cos \frac{k \cdot 2\pi}{n}, \sin \frac{k \cdot 2\pi}{n})$, for the outer nodes $(R + c) \cdot (\cos \frac{k \cdot 2\pi}{n}, \sin \frac{k \cdot 2\pi}{n})$ where $n = 6, k = 1, 2, \dots, 6, R = 2cm, c = 0.5cm$. Distances are given by the Euclidean norm if there is an edge, otherwise ∞ .

• Try to show that Christofides' algorithm always yields a tour which is at most 50% longer than the optimal tour for a metric TSP-instance.

Exercise 9.4

We know that 3SAT is reducible to CLIQUE.

Consider the use of that reduction to approximate Max-3SAT using an approximation for Max-CLIQUE. What happens with the approximation factor?
