

Satisfiability/validity of DNF and CNF

Satisfiability of formulas in DNF can be checked in linear time.

A formula in DNF is satisfiable iff at least one of its conjunctions is satisfiable. A conjunction is satisfiable iff for every atomic formula A the conjunction does not contain both A and $\neg A$ as literals.

Satisfiable: $(\neg B \wedge A \wedge B) \vee (\neg A \wedge C)$

Unsatisfiable: $(A \wedge \neg A \wedge B) \vee (C \wedge \neg C)$

Satisfiability/validity of DNF and CNF

Validity of formulas in CNF can be checked in linear time.

A formula in CNF is valid iff all its disjunctions are valid.

A disjunction is valid iff for some atomic formula A the disjunction contains both A and $\neg A$ as literals (or the disjunction is empty.)

Valid: $(A \vee \neg A \vee B) \wedge (C \vee \neg C)$

Not valid: $(A \vee \neg A) \wedge (\neg A \vee C)$

Satisfiability/validity of DNF and CNF

Theorem: Satisfiability of formulas in **CNF** is NP-complete.

Theorem: Validity of formulas in **DNF** is NP-complete.

Efficient satisfiability checks

In the following:

- A very efficient satisfiability check for the special class of **Horn formulas**.
- Efficient satisfiability checks for arbitrary formulas in CNF: **DPLL, resolution**.

Horn formulas

A formula F in CNF is a **Horn formula** if every disjunction in F contains at most one positive literal.

Notation:

$$(\neg A \vee \neg B \vee C) \text{ becomes } (A \wedge B \rightarrow C)$$

$$(\neg A \vee \neg B) \text{ becomes } (A \wedge B \rightarrow 0)$$

$$A \text{ becomes } (1 \rightarrow A)$$

Satisfiability check for Horn formulas

Input: a Horn formula F .

for every atomic formula A occurring in F **do**

if F has a subformula of the form $(1 \rightarrow A)$

then mark every occurrence of A in F

while F has a subformula G of the form **do**

$A_1 \wedge \dots \wedge A_k \rightarrow B$ or $A_1 \wedge \dots \wedge A_k \rightarrow 0$

and A_1, \dots, A_k are already marked

and B is not yet marked

if G has the first form **then** mark every occurrence of B

else **return** “unsatisfiable” and **halt**

return “satisfiable” and **halt**

Correctness of the marking algorithm

Theorem. The marking algorithm is correct and halts after at most n iterations of the **while** loop, where n is the number of atomic formulas that occur in F .

Proof: (a) **Termination:** after n iterations all atomic formulas are marked, and so the loop condition does not hold.

(b) If “unsatisfiable” then unsatisfiable.

Observe: if the algorithm marks A , then $\mathcal{A}(A) = 1$ for every assignment \mathcal{A} such that $\mathcal{A}(F) = 1$.

Assume $\mathcal{A}(A) = 1$ for some \mathcal{A} . Let $(A_1 \wedge \dots \wedge A_k \rightarrow 0)$ be the subformula causing “unsatisfiable”. Since A_1, \dots, A_k are marked, $\mathcal{A}(A_1) = \dots = \mathcal{A}(A_k) = 1$. Then $\mathcal{A}(A_1 \wedge \dots \wedge A_k \rightarrow 0) = 0$ and so $\mathcal{A}(F) = 0$, contradiction. So F has no satisfying assignments.

(c) If “satisfiable” then satisfiable.

We show that the assignment given by

$$\mathcal{A}(A_i) = 1 \text{ iff } A_i \text{ is marked after termination}$$

satisfies F :

- In every $(A_1 \wedge \dots \wedge A_k \rightarrow B)$ either B is marked or at least one A_i is not marked.
- In every $(A_1 \wedge \dots \wedge A_k \rightarrow 0)$ at least one A_i is not marked (otherwise the algorithm would have terminated with “unsatisfiable”).

Runtime

Let n be the number of atomic formulas in F .

Let m be the length of F .

Step (1) can be executed in $O(nm)$ time (at most two scans of the formula for each variable).

The number of iterations of the **while** loop is bounded by n , and the runtime of an iteration is bounded by m .

Overall runtime: $O(nm)$.

In the next slides we sketch a faster $O(m)$ algorithm.

An $O(m)$ algorithm

Data structure:

- Array of conjuncts, each conjunct stored as a list.
(e.g., $A_1 \wedge A_2 \rightarrow B$ stored as $A_1 \mapsto A_2 \mapsto B$)
- Array of size n , where the i -th element is a list of pointers to all occurrences of A_i on left-hand-sides of conjuncts.
- Single-linked list W of length at most n to store the variables that have been marked but not yet processed.
- Bitvector V of length n to store the variables that have been marked.

An $O(m)$ algorithm

1. $W, V = \{A \mid 1 \rightarrow A \text{ is conjunct of } F \}$ 1, $O(m)$
2. **while** $W \neq \emptyset$ n , $O(n)$
3. pick (and delete) A from W n , $O(n)$
4. **for each** conjunct $G \rightarrow H$ s.t. A occurs in G **do**
5. delete A from G $O(m)$, $O(m)$
6. **if** G is empty **then** $O(m)$, $O(m)$
7. **if** $H = B$ and $B \notin V$ **then** add B to W, V $O(m)$, $O(m)$
8. **else** /* $H = 0$ */ **return** “unsatisfiable” 1, $O(1)$
9. **return** “satisfiable” 1, $O(1)$

For each line we give the number of times it is executed and the total time required by all executions together.

An $O(m)$ algorithm

Correctness argument (informal):

The algorithm mimics the original one. Marking an atomic formula corresponds to adding it to the worklist.

Example: MYCIN

MYCIN: Rule system for treatment of blood infections developed in the 1970s.

Beispiel:

```
IF the infection is primary-bacteremia
AND the site of the culture is one of the
    sterile sites
AND the suspected portal of entry is the
    gastrointestinal tract
THEN there is suggestive evidence (0.7) that
    infection is bacteroid.
```
